

No.	DFS (Depth First Search)	BFS (Breadth First Search)
1	DFS explores a graph depth-wise , going as deep as possible along a path.	BFS explores a graph level-wise , visiting all neighbors first.
2	DFS uses a Stack (either explicit stack or recursion stack).	BFS uses a Queue .
3	DFS uses backtracking to explore remaining paths.	BFS does not use backtracking .
4	DFS is easier to implement using recursion .	BFS recursive implementation is more complex than DFS.
5	DFS requires less memory compared to BFS.	BFS requires more memory because it stores all nodes of a level.
6	DFS does not guarantee the shortest path.	BFS guarantees the shortest path in an unweighted graph.
7	DFS may get stuck exploring a long or infinite path .	BFS always explores nearest nodes first .
8	DFS is useful for cycle detection, topological sorting, and maze solving .	BFS is useful for shortest path, level order traversal, and social networks .
9	In DFS, nodes are visited in a deep order .	In BFS, nodes are visited in a wide (level) order .
10	Time complexity is $O(V + E)$.	Time complexity is $O(V + E)$.
